Case status: Completed

Case notes:

The report:

371480 KW/bs

Ten digitalized radiographic images containing projections of the pelvis and elbows were submitted for evaluation. The radiographs are dated 2/7/17.

Radiographic Findings:

On the hip extended view both femoral heads are located in their respective acetabula and are congruous with the acetabular rims.

Greater than 50% of the femoral heads are located medial to the dorsal acetabular rims on the hip extended view.

On the distracted view, both femoral heads remain in their respective acetabula.

Approximately 40% of the femoral heads are located medial to the dorsal acetabular rims on the distracted views.

Obvious incongruity between the femoral heads and acetabula is not identified on the distracted views.

Muscle volume in both hind legs is within normal limits.

Alignment of the patellae with the femurs is normal.

The anconeal process of both ulnae and proximocranial aspect of both radii are smooth with no evidence of osteophyte formation.

No sclerosis is associated with the ulnar notches.

Both medial coronoid processes are smooth in contour and a fragment associated with the medial coronoid processes is not identified.

Diagnosis: Normal pelvis and elbows.

Comments: Radiographic changes to suggest elbow or hip dysplasia are not present. Based on the OFA

scheme of evaluating hips, the hips would be rated as excellent in conformation. Radiographs obtained at 2 years of age will need to be evaluated to completely exclude elbow and hip dysplasia and to establish a final rating on the coxofemoral joints.
