Case status: Completed

Case notes:

The report:

381953 KW/bs

Eight digitalized radiographic images containing projections of the pelvis and elbows were submitted for evaluation. The radiographs are dated 5/12/17.

Radiographic Findings:

On the hip extended view both femoral heads are located in their respective acetabula and are congruous with the acetabular rims.

Greater than 50% of the femoral heads are located medial to the dorsal acetabular rims.

On the distracted view, both femoral heads remain in their respective acetabula with approximately 40% of the right femoral head and 30% of the left femoral head located medial to the dorsal acetabular rims.

There is widening of the coxofemoral joints on the distracted views.

No osteophyte formation is present on the femoral necks or acetabula.

Alignment of the patellae with the femurs is normal.

Muscle volume in both hind legs is within normal limits.

The anconeal process of both ulnae and proximocranial aspect of both radii are smooth with no evidence of osteophyte formation.

No sclerosis is associated with the ulnar notches.

Both medial coronoid processes are smooth in contour and a fragment associated with the medial coronoid processes is not identified.

Diagnosis: Normal pelvis and elbows.

Comments: Radiographic changes to suggest elbow or hip dysplasia are not present. Based on the hip extended view of the pelvic, the coxofemoral joints would be rated as good in conformation. Radiographs

obtained at 2 years of age will need to be evaluated to completely exclude elbow and hip dysplasia and to establish a final rating on the coxofemoral joints.
